The Series STR-F6600 is specifically designed to satisfy the requirements for increased integration and reliability in off-line quasi-resonant flyback converters. The series incorporates a primary control and drive circuit with discrete avalanche-rated power MOSFETs.

Covering the power range from below 25 watts up to 300 watts for 100/115/230 VAC inputs, and up to 150 watts for 85 to 265 VAC universal input, these devices can be used in a range of applications, from battery chargers and set top boxes, to televisions, monitors, and industrial power supply units.

Cycle-by-cycle current limiting, under-voltage lockout with hysteresis, over-voltage protection, and thermal shutdown protects the power supply during the normal overload and fault conditions. Over-voltage protection and thermal shutdown are latched after a short delay. The latch may be reset by cycling the input supply. Low-current startup and a low-power standby mode selected from the secondary circuit completes a comprehensive suite of features. The series is provided in a five-pin overmolded TO-3P style package, affording dielectric isolation without compromising thermal characteristics.

#### **FEATURES**

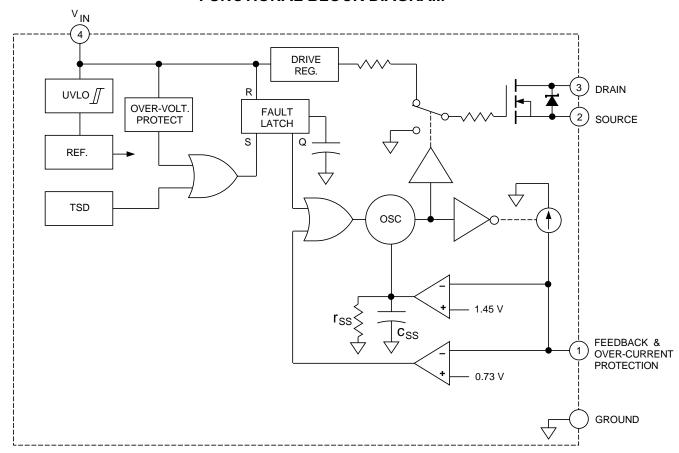

- Flyback Operation with Quasi-Resonant Soft Switching for Low Power Dissipation and EMI
- Rugged Avalanche-Rated MOSFET
- Choice of MOSFET Voltage and  $r_{DS(on)}$
- Full Over-Current Protection (no blanking)
- Under-Voltage Lockout with Hysteresis
- Over-Voltage Protection
- Direct Voltage Feedback
- Low Start-up Current (<400 µA)
- Low-Frequency, Low-Power Standby Operation
- Overmolded 5-Pin Package

Always order by complete part number, e.g., STR-F6652.

# **Functional Description and Operation**

The voltage on the  $V_{\rm IN}$  terminal (pin 4) controls startup and shutdown of the Series STR-F6600 devices.

Figure 1 shows a typical start up circuit. The  $V_{\rm IN}$  terminal voltage during startup is shown in figure 2.

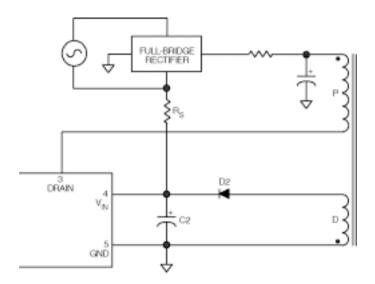

Figure 1 - Start-Up Circuit

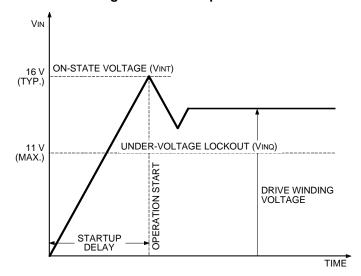

Figure 2 – Waveform of V<sub>IN</sub> Terminal Voltage at Startup

At startup, C2 is charged through the startup resistor  $R_s$ . When the  $V_{\rm IN}$  terminal voltage reaches 16 V (typ.), the control circuit enables regulator operation. Once the regulator starts, it draws up to 30 mA from C2 causing the voltage on C2 to fall momentarily. Once the regulator output voltage is established, the drive winding D starts to charge C2 via D2. The voltage on C2 thus recovers to the nominal drive voltage (18 V).

As shown in figure 3, the input current is below  $100 \,\mu\text{A}$  (at  $T_{\text{M}} = 25\,^{\circ}\text{C}$ ) prior to control circuit turn on. The latch circuit holding current is  $400 \,\mu\text{A}$  (max.). To ensure latch operation, the current in  $R_{\text{S}}$  at the lowest ac input voltage should be at least  $500 \,\mu\text{A}$ .

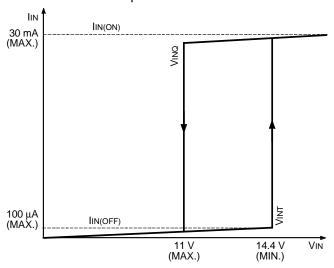

Figure 3 – Supply Terminal Current, I,

The value of  $R_S$  thus determines the charge time of C2 and thus the startup delay.  $R_S$  is typicaly 68 k $\Omega$  for wide operation (90 V ac to 265 V ac) and 100 k $\Omega$  for 220 volt ac operation.

The choice of C2 is a compromise between an acceptable startup delay (in conjunction with  $R_{\rm S})$  and a hold-up time sufficient to keep pin 4 above its under-voltage shutdown threshold of 11 V. Typically C2 is in the range of 47  $\mu F$  to 100  $\mu F$ .

continued, next page...

The drive winding voltage is set such that in normal operation the C2 voltage is above the specified maximum shutdown voltage (11 V) and below the specified minimum over-voltage threshold (20.5 V).

In applications where there is a significant variation in load current, the  $V_{\rm IN}$  terminal voltage may vary, as shown in figure 4. This is due to peak charging of C2. In this case, adding a resistor in the range of a few ohms to tens of ohms in series with the rectifier diode D2 will bring the voltage variation within limits.

## Soft Start, Quasi Resonant and Voltage Regulation

Refer to the Functional Block Diagram and the Typical Application Diagram (figure 6). The internal oscillator uses the charge/discharge of an internal 4700 pF capacitor ( $c_{SS}$ ) to generate the MOSFET drive signals.

The regulator has two modes of operation:

- 1. fixed 50 µs off time (soft start) and
- 2. demagnetization sensing quasi-resonant mode normal operation.

In both cases, voltage regulation is achieved by taking the composite optocoupled voltage error and superimposed drain current ramp (current-mode control) and comparing this to an internal 0.73 V reference. The FBK/OCP comparator output pre-terminates the oscillator, which turns off the MOSFET drive signal.

The MOSFET is turned on again when either  $c_{SS}$  discharges or a quasi-resonance signal is detected on pin 1.

## Fixed 50 µs Off-Time: Soft-Start Mode

This is the mode of operation in the absence of a quasiresonance signal on pin 1 (see figure 5), and occurs at

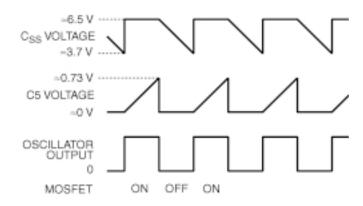

Figure 5 – Soft-Start Operation

startup and in overload. It also can be commanded externally to provide low-power standby operation.

In the absence of a feedback signal (such as at startup, or a short circuit) the drain current ramp, sensed across R5 and noise filtered by R4/C5 appears on pin 1. When the ramp voltage on C5 exceeds the 0.73 V reference signal, the FBK/OCP comparator changes state, shutting down the oscillator and turning off the MOSFET. Thus the voltage on  $c_{SS}$  is held high (6.5 V) by the comparator. When the comparator changes state,  $c_{SS}$  discharges via  $r_{SS}$ ; the voltage on  $c_{SS}$  ramps down until it reaches 3.7 V. The oscillator turns on the MOSFET. This ramp-down time is internally trimmed to 50  $\mu s$ . The comparator changes state again and the cycle repeats. Thus in the absence of feedback, the current-sense resistor R5 accurately controls the MOSFET maximum current.

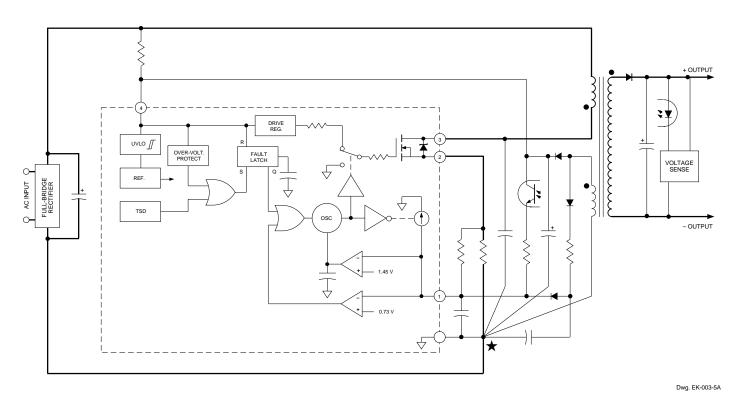

Figure 6 – Series STR-F6600 Typical Application

**WARNING** — These devices are designed to be operated at lethal voltages and energy levels. Circuit designs that embody these components must conform with applicable safety requirements. Precautions must be taken to prevent accidental contact with power-line potentials. Do not connect grounded test equipment.

The use of an isolation transformer is recommended during circuit development and breadboarding.

# Soft Start with Voltage Feedback (refer to figure 7)

Output voltage control is achieved by sensing the optocoupled feedback current (proportional to the output voltage error signal) across resistor R4 and summing this with the drain current ramp on R5. The signal on pin 1 is therefore the opposite of the output voltage error signal and the drain current ramp. The dc bias signal across R4 is thus a function of the load. Consequently at light load, the bias signal on R4 is closer to the threshold voltage of the comparator. To eliminate the possibility of false shutdown at MOSFET turn on (when there is a current spike due to the discharge of primary capacitance), a constant-current sink of 1.35 mA is turned on, effectively lowering the input impedance on pin 1, and momentarily increasing the shutdown threshold.

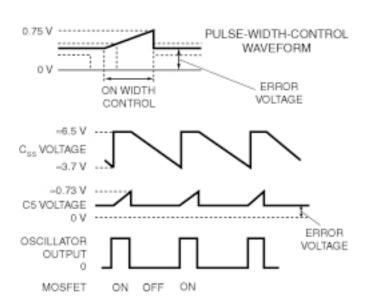

Figure 7 - Voltage Regulation Waveforms

#### **Normal Operation (Quasi-Resonant) Mode**

Refer to the Functional Block Diagram, Typical Application diagram (figure 6), and Quasi-Resonance Waveforms (figure 8).

Regulation is achieved as in fixed off-time mode but instead of having a fixed off-time, the demagnetization of the transformer is sensed by a second comparator. This comparator threshold,  $V_{\text{th}(2)}$  is nominally 1.45 V. Quasiresonance sensing makes use of the natural magnetizing and leakage inductances and self-capacitances of the power circuit.

Figure 8 shows the drain voltage waveform,  $(V_{DS})$ , on pin 3 of the STR-F66xx, as well as  $V_p$ , the voltage on the primary of the transformer.

Once the current in the output diode stops flowing, the primary stored energy 'rings' as shown by  $V_p$  and  $V_{DS}$ .

The resonant frequency  $(f_r)$  is determined by the magnetizing inductance of the transformer and the capacitor C4.

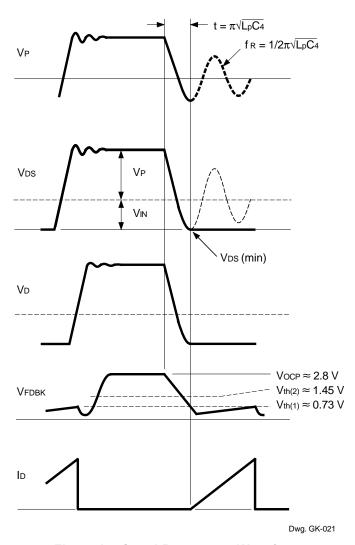

Figure 8 – Quasi-Resonance Waveforms

The addition of this capacitor sets the ringing frequency and reduces the harmonic content in the  $V_{DS}$  waveform, lowering EMI. Also since  $V_{DS}$  falls to a minimum during the first half-cycle of the ring this point can be sensed and used to turn on the MOSFET with minimum voltage across it. Thus the MOSFET is low voltage and zero current switched (LVS/ZCS).

The voltage  $V_{\rm OCP}$  (pin 1) has the same form as the  $V_{\rm DS}$  waveform. The condition for quasi-resonant operation is given by:

$$2.0 \text{ V} < \text{V}_{\text{OCP}} > 5.5 \text{ V for} > 1 \text{ } \mu\text{s}$$

Transformer design is exactly as for any other discontinuous-mode type flyback.

For optimum EMI/efficiency performance, quasiresonance turn off is achieved when the MOSFET is at zero voltage and zero current; that is, at one half cycle of the quasi-resonance frequency,  $f_{\rm r}$ .

# **Over-Current Protection (OCP) Functions**

Refer to the Functional Block diagram and Typical Application diagram (figure 6).

The regulator implements pulse-by-pulse over-current protection, which limits the maximum drain current in the MOSFET on every pulse by switching off the internal drive to the MOSFET, and the MOSFET drain current is detected across R5.

#### **Drive Circuit**

Refer to the Functional Block Diagram.

This circuit is driven from the oscillator and provides the current drive to charge and discharge the MOSFET gate-source capacitance, thereby switching the device on and off. The basic circuit configuration is totem-pole type with an additional limiting resistor in the gate circuit at turn on. This limits the turn on speed of the MOSFET, thereby reducing EMI due to the discharge of primary capacitance. This is possible because of the low-voltage switching, zero-current switching nature of the turn on.

The value of the turn-off resistance is lower, allowing the device turn-off current to be increased. This reduces the turn-off loss in the MOSFET.

The gate drive voltage (8.3 V) is such that even with 0.73 V across R5 (drain current sense resistor), the MOSFET is fully enhanced, allowing full use to be made of its high current handling capacity.

#### **Latch Circuit**

The latch circuit keeps the oscillator output low to inhibit operation of the regulator when over-voltage protection (OVP) and thermal shutdown (TSD) circuits are in operation. As long as the latch hold-in current is 400  $\mu A$  (max., supplied via  $R_{\rm S}$ ) with  $V_{\rm IN}$  at 8.5 V (pin 4), the regulator will stay in the off state.

An internal noise filter provides 10 µs of noise immunity to prevent spurious operation of the over-voltage protection or thermal shutdown.

With the latch 'on', the voltage on pin 4 cycles between 16 V and 10 V as shown in figure 9. This is due to the higher current drawn when the pin 4 is at 16 V compared to that drawn close to shutdown (10 V).

Pulling  $V_{\rm IN}$  (pin 4) below 6.5 V will reset the latch circuit, re-enabling the regulator.

#### Thermal Shutdown

This internal feature triggers the latch if the internal frame temperature exceeds  $140^{\circ}$ C (typ.).

The temperature is sensed on the control IC, but also protects against overheating of the MOSFET as the MOSFET and the control IC are mounted on the same lead frame. Additionally, protection is provided for other onboard components.

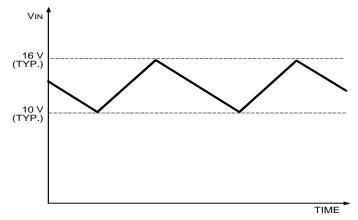

Figure 9 – Example of V<sub>IN</sub> Terminal Voltage Waveform at Latch Circuit On

### **Over-Voltage Protection Circuit**

This feature of the STR-F66xx triggers the latch circuit when the  $V_{\rm IN}$  voltage (pin 4) exceeds 22.5 V (typ.). Because the voltage on pin 4 is proportional to the output voltage (they are linked by the transformer turns ratio), the regulator protects the output against over-voltage. This function is entirely independant of the output-voltage regulation loop and indeed will protect against output over-voltage should the voltage error signal be lost. The measure of over-voltage is given by:

$$V_{OUT(OVP)} = V_{OUT(NOM)} \times V_{IN(OVP)} / V_{IN(NOM)}$$
 where  $V_{IN(OVP)}$  is the drive voltage on pin 4.

In an over-voltage sensitive application, the drive voltage can be set to close to 20 V and thus will protect the output, if it rises more than 10% above nominal.

## **Capacitors**

Electrolytic capacitors carrying large switching frequency ripple currents (C1 and the output capacitors) should be capable of handling the high rms currents involved. Capacitors with low ESR are suitable. The quasi-resonance capacitor C4 should be a high-voltage ceramic type suitable for pulsed current operation.

The safety critical nature of the off-line application must be considered when selecting both X and Y capacitors for common- and differential-mode noise filtering. Use of the low-noise quasi-resonant Series STR-F6600 will allow optimization of these capacitor values.

C5, the 470 pF filtering capacitor should be a 50 V temperature-stable (COG) ceramic type.

#### Resistors

Resistor R5 carries high-frequency current, and so a low internal inductance type of 1 W rating should be used.

Resistor R9 (R<sub>s</sub>) should be 2 W metal oxide.

All other resistors can be 1/4 watt or 1/2 watt metal film.

## **Diodes**

Diodes carrying the high-frequency flyback currents (such as the transformer rectifier diodes) should have a fast or ultrafast reverse-recovery characteristic, adequate current handing and peak reverse-voltage rating. Allegro/Sanken supplies a range of suitable diodes, and these are described in the Allegro/Sanken short-form catalogue (AMS-127) or latest issue of Bulletin D01EC0.

## **Optocoupler**

Both Toshiba TLP 621 and Siemens SFH 610A2 or 615A2 are suitable. A current-transfer ratio of 50% to 200% is acceptable.

## **Error Amplifier**

A standard TL431 transconductance amplifier or an Allegro/Sanken Series SE error-amplifier IC can be used. The Series SE is particularly well-suited to high-voltage (70 V to 140 V) power outputs.

If a Series SE error-amplifier IC is used, normally phase compensation is not required. Should additional high-frequency attenuation be required, a capacitor (0.022  $\mu F$  or less) can be connected across the primary side (collectoremitter) of the optocoupler, a diode to maintain quasi-resonant operation should be added in series with the phototransistor emitter.
